The following are a list of vDPA (vHost Data Path Acceleration) device drivers, which can be used from an application through vhost API.
OVERVIEW OF VDPA DRIVERS FEATURES

This section explains the supported features that are listed in the table below.

csum Device can handle packets with partial checksum.

guest csum Guest can handle packets with partial checksum.

mac Device has given MAC address.

gso Device can handle packets with any GSO type.

guest tso4 Guest can receive TSOv4.

guest tso6 Guest can receive TSOv6.

ecn Device can receive TSO with ECN.

ufo Device can receive UFO.

host tso4 Device can receive TSOv4.

host tso6 Device can receive TSOv6.

mrg rxbuf Guest can merge receive buffers.

ctrl vq Control channel is available.

ctrl rx Control channel RX mode support.

any layout Device can handle any descriptor layout.

guest announce Guest can send gratuitous packets.

mq Device supports Receive Flow Steering.

version 1 v1.0 compliant.

log all Device can log all write descriptors (live migration).

indirect desc Indirect buffer descriptors support.

event idx Support for avail_idx and used_idx fields.

mtu Host can advise the guest with its maximum supported MTU.

in_order Device can use descriptors in ring order.

IOMMU platform Device support IOMMU addresses.

packed Device support packed virtio queues.

proto mq Support the number of queues query.
proto log shmfd  Guest support setting log base.
proto rarp  Host can broadcast a fake RARP after live migration.
proto reply ack  Host support requested operation status ack.
proto host notifier  Host can register memory region based host notifiers.
proto pagefault  Slave expose page-fault FD for migration process.
BSD nic_uio  BSD nic_uio module supported.
Linux VFIO  Works with vfio-pci kernel module.
Other kdrv  Kernel module other than above ones supported.
ARMv7  Support armv7 architecture.
ARMv8  Support armv8a (64bit) architecture.
Power8  Support PowerPC architecture.
x86-32  Support 32bits x86 architecture.
x86-64  Support 64bits x86 architecture.
Usage doc  Documentation describes usage. In doc/guides/vdpadevs/.
Design doc  Documentation describes design. In doc/guides/vdpadevs/.
Perf doc  Documentation describes performance values. In doc/perf/.

Note:  Most of the features capabilities should be provided by the drivers via the next vDPA operations: get_features and get_protocol_features.

**Note:** Features marked with “P” are partially supported. Refer to the appropriate driver guide in the following sections for details.
The IFCVF vDPA (vhost data path acceleration) driver provides support for the Intel FPGA 100G VF (IFCVF). IFCVF’s datapath is virtio ring compatible, it works as a HW vhost backend which can send/receive packets to/from virtio directly by DMA. Besides, it supports dirty page logging and device state report/restore, this driver enables its vDPA functionality.

4.1 Pre-Installation Configuration

4.1.1 Config File Options

The following option can be modified in the config file.

- CONFIG_RTE_LIBRTE_IFC_PMD (default y for linux)
  Toggle compilation of the librte_pmd_ifc driver.

4.2 IFCVF vDPA Implementation

IFCVF’s vendor ID and device ID are same as that of virtio net pci device, with its specific subsystem vendor ID and device ID. To let the device be probed by IFCVF driver, adding “vdpa=1” parameter helps to specify that this device is to be used in vDPA mode, rather than polling mode, virtio pmd will skip when it detects this message. If no this parameter specified, device will not be used as a vDPA device, and it will be driven by virtio pmd.

Different VF devices serve different virtio frontends which are in different VMs, so each VF needs to have its own DMA address translation service. During the driver probe a new container is created for this device, with this container vDPA driver can program DMA remapping table with the VM’s memory region information.

The device argument “sw-live-migration=1” will configure the driver into SW assisted live migration mode. In this mode, the driver will set up a SW relay thread when LM happens, this thread will help device to log dirty pages. Thus this mode does not require HW to implement a dirty page logging function block, but will consume some percentage of CPU resource depending on the network throughput. If no this parameter specified, driver will rely on device’s logging capability.

4.2.1 Key IFCVF vDPA driver ops

- ifcvf_dev_config: Enable VF data path with virtio information provided by vhost lib, including IOMMU programming to enable VF DMA to VM’s memory, VFIO interrupt setup to route HW
interrupt to virtio driver, create notify relay thread to translate virtio driver’s kick to a MMIO write onto HW, HW queues configuration.

This function gets called to set up HW data path backend when virtio driver in VM gets ready.
• ifcvf_dev_close: Revoke all the setup in ifcvf_dev_config.

This function gets called when virtio driver stops device in VM.

4.2.2 To create a vhost port with IFC VF

• Create a vhost socket and assign aVF’s device ID to this socket via vhost API. When QEMU vhost connection gets ready, the assigned VF will get configured automatically.

4.3 Features

Features of the IFCVF driver are:
• Compatibility with virtio 0.95 and 1.0.
• SW assisted vDPA live migration.

4.4 Prerequisites

• Platform with IOMMU feature. IFC VF needs address translation service to Rx/Tx directly with virtio driver in VM.

4.5 Limitations

4.5.1 Dependency on vfio-pci

vDPA driver needs to setup VF MSIX interrupts, each queue’s interrupt vector is mapped to a callfd associated with a virtio ring. Currently only vfio-pci allows multiple interrupts, so the IFCVF driver is dependent on vfio-pci.

4.5.2 Live Migration with VIRTIO_NET_F_GUEST_ANNOUNCE

IFC VF doesn’t support RARP packet generation, virtio frontend supporting VIRTIO_NET_F_GUEST_ANNOUNCE feature can help to do that.
CHAPTER
FIVE

MLX5 VDPA DRIVER

The MLX5 vDPA (vhost data path acceleration) driver library (librte_pmd_mlx5_vdpa) provides support for Mellanox ConnectX-6, Mellanox ConnectX-6 Dx and Mellanox BlueField families of 10/25/40/50/100/200 Gb/s adapters as well as their virtual functions (VF) in SR-IOV context.

Note: Due to external dependencies, this driver is disabled in default configuration of the “make” build. It can be enabled with CONFIG_RTE_LIBRTE_MLX5_VDPA_PMD=y or by using “meson” build system which will detect dependencies.

5.1 Design

For security reasons and robustness, this driver only deals with virtual memory addresses. The way resources allocations are handled by the kernel, combined with hardware specifications that allow to handle virtual memory addresses directly, ensure that DPDK applications cannot access random physical memory (or memory that does not belong to the current process).

The PMD can use libibverbs and libmlx5 to access the device firmware or directly the hardware components. There are different levels of objects and bypassing abilities to get the best performances:

- Verbs is a complete high-level generic API
- Direct Verbs is a device-specific API
- DevX allows to access firmware objects
- Direct Rules manages flow steering at low-level hardware layer

Enabling librte_pmd_mlx5_vdpa causes DPDK applications to be linked against libibverbs.

A Mellanox mlx5 PCI device can be probed by either net/mlx5 driver or vdpa/mlx5 driver but not in parallel. Hence, the user should decide the driver by the class parameter in the device argument list. By default, the mlx5 device will be probed by the net/mlx5 driver.

5.2 Supported NICs

- Mellanox® ConnectX®-6 200G MCX654106A-HCAT (2x200G)
- Mellanox® ConnectX®-6 Dx EN 100G MCX623106AN-CDAT (2x100G)
- Mellanox® ConnectX®-6 Dx EN 200G MCX623105AN-VDAT (1x200G)
5.3 Prerequisites

- Mellanox OFED version: 5.0 see ../../nics/mlx5 guide for more Mellanox OFED details.

5.3.1 Compilation options

These options can be modified in the .config file.

- **CONFIG_RTE_LIBRTE_MLX5_VDPA_PMD (default n)**
  Toggle compilation of librte_pmd_ml5 itself.

- **CONFIG_RTE_IBVERBS_LINK_DLOPEN (default n)**
  Build PMD with additional code to make it loadable without hard dependencies on libibverbs nor libmlx5, which may not be installed on the target system.
  In this mode, their presence is still required for it to run properly, however their absence won’t prevent a DPDK application from starting (with CONFIG_RTE_BUILD_SHARED_LIB disabled) and they won’t show up as missing with ldd(1).
  It works by moving these dependencies to a purpose-built rdma-core “glue” plug-in which must either be installed in a directory whose name is based on CONFIG_RTE_EAL_PMD_PATH suffixed with -glue if set, or in a standard location for the dynamic linker (e.g. /lib) if left to the default empty string ("").
  This option has no performance impact.

- **CONFIG_RTE_IBVERBS_LINK_STATIC (default n)**
  Embed static flavor of the dependencies libibverbs and libmlx5 in the PMD shared library or the executable static binary.

---

**Note:** For BlueField, target should be set to arm64-bluefield-linux-gcc. This will enable CONFIG_RTE_LIBRTE_MLX5_VDPA_PMD and set RTE_CACHE_LINE_SIZE to 64. Default armv8a configuration of make build and meson build set it to 128 then brings performance degradation.

5.3.2 Run-time configuration

- **ethtool** operations on related kernel interfaces also affect the PMD.
  - **class parameter [string]**
    Select the class of the driver that should probe the device. *vdpa* for the mlx5 vDPA driver.
